The Evaluator Due Oct 19

Now that you have finished the reader and the parser, write the following function.

NUMBER eval (EXP e, ENV rho)

This is called from the main (see lisphelp) by the following calls:

currentExp = parseExp();

prValue(eval(currentExp, emptyEnv()));

- The function eval should evaluate (compute) the value of the expression and return the Value, which is an integer (NUMBER).
- The semantics for each operator (loop, block, if, print, *, + , …) specified in the first document given to you. Your evaluator must implement each of these operators
- To Evaluate an expression the correct environment should be made available. Note the initial environment is set to empty

When computing a function (say: f exp_1, exp_2,…exp_ n), the correct environment should be provided (built). You do this by taking the formal arguments from the function record args and the actuals arguments by evaluating exp_1, exp_2,…exp_n and making an environment.
